

Six questions to send Huawei

The first one is worth more than the other five together.

1

What does one full-wave simulation of this component cost?

Every speed claim in the brief is a ratio against this number.

2

What is the acceptance specification across 1.2 to 1.7 GHz?

Reflection, coupling and isolation limits. Yield is meaningless without it.

3

Which parameters are design choices, and which are process noise?

This split decides the whole redesign study.

4

What is the nominal design the tolerances perturb?

The widths are deviations from a value the file does not contain.

5

Do you have field or geometry data for these structures?

If yes, a true physics-informed network becomes possible.

6

What are the units of the copper thickness and the width deviations?

Needed before any tolerance advice can reach a manufacturing engineer.
